United States Energy Consumption in 2024: 94.6 Quads

Lawrence Livermore National Laboratory

Source: LLNL July, 2026. Data is based on DOE/EIA SEDS (2026). If this information or a reproduction of it is used, credit must be given to the Lawrence Livermore National Laboratory and the Department of Energy, under whose auspices the work was performed. Distributed electricity represents only retail electricity sales and does not include self-generation. Per the October 2023 methodology update, EIA reports consumption of noncombustible renewable energy for electricity generation (i.e., hydro, wind, geothermal and solar) using the captured energy approach, which applies a constant conversion factor of 3,412 British thermal units per kilowatthour (Btu/kWh), that is, the heat content of electricity. This approach is a change from EIA's old methodology, called the fossil fuel equivalency approach. The efficiency of electricity production is calculated as the total retail electricity delivered divided by the primary energy input into electricity generation. End use efficiency is estimated as 65% for the residential sector, 65% for the commercial sector, 49% for the industrial sector, and 21% for the transportation sector. Totals may not equal sum of components due to independent rounding. LLNL-MI-410527
